COMPLETE SPECIFICATION
PROVISIONAL PATENT

COMMUNICATION APPARATUS AND HELMET

The invention is described in the following statement:

COMMUNICATION APPARATUS AND HELMET

FIELD OF THE INVENTION

The present invention is concerned with improved means for facilitating communication
5 by workers in noisy and hazardous environments.

BACKGROUND TO THE INVENTION

A problem that is particularly faced by workers, such as fire-fighters, in noisy and often
hazardous environments, is that it is difficult to clearly communicate with fellow workers,
10 and other parties, when wearing apparatus such as helmets and breathing masks. Several
approaches to this problem are described in the prior art. For example, in Japanese
Patent Application publication No. JP 11215581-A to Temco Japan Co. Ltd, there is
described a bone conduction head-set suitable for mounting under a helmet. The bone
conduction microphone is mounted on the top of the head. Such an apparatus is believed
15 to be potentially dangerous as in the event of a load falling upon a wearer of the apparatus
the bone conduction microphone may depress the wearer's skull. Other approaches to
facilitating communication have involved the use of headphones which cover the ears.
While such an approach allows the wearer to readily hear sound from the headphones it
prevents the wearer from hearing ambient noise and engaging in direct communication
20 with those nearby.

Where personnel operate in high ambient noise environments there may be a need
for hearing protection to be used. However, the use of hearing protection typically
interferes with the provision of clear communication.

A further problem that is faced in providing a communication means for firefighters
25 is that the communication means may be damaged by water used by the firefighters in the
course of their work.

It is an objective of the present invention to provide means for addressing the
above described problems.

SUMMARY OF THE INVENTION

According to one aspect of the present invention there is provided a speaker enclosure including:

- 5 a housing disposed about a speaker, the housing having at least one opening;
- a resilient diaphragm attached to the housing for contact with the head of a person in use; and
- a membrane sealing the at least one opening thereby shielding the speaker from water.

10 In a preferred embodiment the housing has first and second openings wherein the resilient diaphragm seals the first opening for contact with the head of a person in use and the second opening is sealed by the waterproof membrane.

Preferably the second opening is protected by an acoustically transparent cover.

In a preferred embodiment a cone of the speaker faces the membrane and acoustically transparent cover.

15 It is desirable that the housing be dimensioned so that in use energy transfer from the speaker to the person via the resilient diaphragm is maximised.

An electrical cable is typically coupled to the speaker.

Preferably the housing includes an aperture and the electrical cable passes through the aperture.

20 It is desirable that the aperture be filled with a sealant.

Preferably the sealant provides strain relief to the electrical cable.

Preferably the housing includes a mounting means that may be configured to receive a strap, belt or the like.

25 A transducer may be located inside the housing adjacent to the resilient diaphragm in order that the speaker enclosure be used to pick-up vibrations from a wearer as well as to transfer vibrations to the wearer. Preferably the transducer is an accelerometer.

The accelerometer is preferably acoustically insulated, for example by means of a visco-elastic layer. A spacer may be attached between the visco-elastic layer and the speaker.

30 According to a further aspect of the invention there is provided a vibration conduction microphone including:

- a transducer;
- an acoustic isolator disposed about the accelerometer; and
- a housing.

Preferably the acoustic isolator includes a visco-elastic material

Preferably the acoustic isolator further includes a holder for holding the visco-elastic material.

In a preferred embodiment the transducer comprises an accelerometer.

5 In one embodiment the housing is a flexible body of, for example, urethane, configured to receive the accelerometer, acoustic isolator and holder.

The housing may include a mounting means. The mounting means may be configured to receive a strap, belt or the like.

10 According to another aspect of the present invention there is provided a helmet mounting, including transducing means consisting of a vibration conduction microphone and/or a speaker enclosure;

wherein, the transducing means is mounted at the rear of the helmet so that in use the transducing means contacts the rear of a wearer's head.

15 Preferably the helmet mounting includes both the vibration conduction microphone and the speaker conduction.

Preferably the vibration conduction microphone is of the type previously described. Similarly it is preferable that the speaker enclosure is of the type previously described.

20 The transducing means may be conveniently mounted to, or suspended from, an internal headband or nape strap of the helmet.

The helmet mounting may be provided in combination with a helmet or alternatively it may be provided separately for retro-fitting to a helmet.

25 Other preferred features of the invention will be apparent from the following detailed description wherein the invention will be explained in relation to a number of exemplary drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

30 In order that this invention may be more readily understood and put into practical effect, reference will now be made to the accompanying drawings which illustrate typical preferred embodiments of the invention:

Figure 1 is a first perspective view of a speaker enclosure according to an embodiment of an aspect of the invention.

Figure 2 is a second perspective view of the speaker enclosure of Figure 1.

Figure 3 is a plan view of the speaker enclosure of Figures 1 and 2

Figure 3A is a cross-sectional view of the speaker enclosure of Figures 1 and 2.

Figure 4 is a perspective view of a speaker enclosure according to a further embodiment of the invention.

Figure 5 is a plan view of the speaker enclosure of Figure 4

5 Figure 5A is a cross sectional view of the speaker enclosure of Figures 4 and 5.

Figure 6 is a first perspective view of a vibration conduction microphone according to an embodiment of another aspect of the present invention.

Figure 7 is a second perspective view of the vibration conduction microphone of Figure 6.

10 Figure 8 is a plan view of the vibration conduction microphone of Figures 6 and 7.

Figure 8A is a cross-sectional view of the vibration conduction microphone of Figures 6 and 7.

Figure 9 depicts a use of the speaker enclosure of Figure 1 and the vibration conduction microphone of Figure 6.

15 Figure 10 is a first perspective view of a helmet mounting according to a further aspect of the invention.

Figure 11 is a second perspective view of the helmet mounting of figure 10

Figure 12 is a plan view of the helmet mounting of Figures 10 and 11

Figures 12A and 12B are cross sectional views.

20 Figure 13 is an external view of a typical helmet

Figure 14 is a view of the interior of said typical helmet showing the position of the helmet mounting of Figure 10 in use.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

25 Figure 1 is a perspective view of a first side of a speaker enclosure according to a preferred embodiment of the present invention. The term "speaker enclosure" is used herein to refer to a loaded speaker enclosure, i.e., one including a speaker. The speaker enclosure includes a housing 2 which incorporates a mounting means in the form of slots 3 arranged for securing the speaker enclosure to a belt, strap or the like. A cover in the form of a grill 4 covers one end of housing 2. The grill is acoustically transparent due to a number of perforations 5 to allow the escape of sound from a speaker located in the housing 2. A cable 6 protrudes through a port 7 formed in housing 2. Cable 6 is connected to a speaker located in the housing 2 as will be shortly explained.

30

Figure 2 is a further perspective view of the speaker enclosure showing a diaphragm 8 which is incorporated into housing 2 opposite grill 4. Figure 3A is a cross section through the speaker enclosure showing an internally located speaker 9 with cone 10 facing grill 4 as shown. Between the speaker cone and the grill there is located a waterproof membrane 11. Port 7 is sealed with a waterproof sealant 12 which surrounds cable 6 and provides strain relief to the cable. It will be realised that the inside of the speaker enclosure is waterproofed by virtue of membrane 11, diaphragm 8 and sealant 12.

In use, the speaker enclosure is mounted to the side of the head, by means of a band or strap through slots 3, so that diaphragm 8 is brought into contact with the side of the head but preferably not over the ear. An electrical signal from some communication source, for example a walkie-talkie radio, is applied by means of cable 6 to speaker 9. In response speaker cone 10 vibrates so that sound may be heard emanating from grill 4. Simultaneously diaphragm 8 vibrates against the side of the head thereby causing the auricles of the ear to vibrate sympathetically and allowing the hearer to perceive communication. The depth of the housing, indicated by dimension D in Figure 3A, is tuned to maximise the coupling of energy from speaker 9 into the wearer's head via diaphragm 8.

Figure 4 is a perspective view of a speaker enclosure according to a further embodiment of the invention. Figure 5A is a cross section of the speaker enclosure of Figure 4. An acoustic isolator 13, which preferably includes a visco-elastic material such as Sorbothane®, surrounds a transducer in the form of accelerometer 14. A preferred accelerometer is the Knowles Corporation's 1771 single axis accelerometer. The acoustic isolator further includes a transducer cup 15 which anchors the visco-elastic material and which is secured to the rear of speaker 16. Cabling 17 from accelerometer 14 runs out through port 18 along with cabling 17 from speaker 16. In use, resilient diaphragm 19, is placed against the head of a person. In order to transmit a voice signal to the person, speaker 16 is appropriately energised. Vibrations from the speaker are transmitted via resilient diaphragm 19 into the head of the person where they cause sympathetic vibration of the auricles thereby causing the person to perceive the voice signal. Sound waves generated by speaker 16 also emanate out through membrane 20 and grill 21 and are heard by the person in the normal way. Conversely when the person speaks vibrations pass through resilient diaphragm 19, are picked up by accelerometer 14 and transduced into an electrical signal that is conveyed by cable 17 for further processing. The

accelerometer is prevented from picking-up spurious external sounds by acoustic isolator 13.

Figure 6 is a perspective view of a vibration conduction microphone according to a preferred embodiment of a further aspect of the present invention. Figure 7 is a second perspective view of vibration conduction microphone of figure 6, Figure 8A is a cross sectional view of the vibration conduction microphone of Figures 6 and 7. Housing 22 has slots 23 for receiving a strap or belt for mounting the microphone to the head of a wearer and incorporates a diaphragm 24. Preferably housing 22 is a flexible body of, for example, urethane. Housing 22 has a recess 26. An acoustic isolator 25 which includes a visco-elastic material such as Sorbothane, surrounds a transducer in the form of an accelerometer 27. A preferred accelerometer is the Knowles Corporation's 1771 single axis accelerometer. The acoustic isolator a transducer holder in the form of cup 28 which is secured into recess 26 by means of waterproof sealant (not shown). A cable 29 protrudes through a port 30 formed in housing 22. Cable 29 is connected to the accelerometer for conveying electrical signals generated by the accelerometer during use for processing. A flexible waterproof sealant 31 seals port 30. It will be realised that the inside of housing 22 is waterproofed by virtue of diaphragm 24 and sealant 31. In use the vibration conduction microphone is secured to the head of a wearer by threading a belt or strap through slots 23 and securing it with diaphragm 24 against the wearer's head. As the wearer speaks, vibrations corresponding to the speech are produced and these are conveyed to the accelerometer 27 which converts them into electrical signals that are conveyed by cable 29 for processing by suitable electronic circuitry.

Figure 9 shows a person 32 wearing a typical breathing apparatus mask 33 that includes a number of straps 34 and 35. Attached to strap 34 is the vibration conduction microphone 36 of Figure 6. Attached to strap 35 is the speaker enclosure of Figure 1. Cabling 37 from the microphone 36 and the speaker enclosure 38 is connected to suitable electronic communication modules.

The communication modules may include signal conditioning circuitry such as filters to improve the clarity of the communications. It will be noted that the wearer's ear 39 is not covered by speaker enclosure 38 so that the wearer may readily hear ambient sound or wear hearing protection in areas of high ambient noise.

Figure 10 is a first perspective view of helmet mount according to an embodiment of a further aspect of the present invention.

Figure 11 is a second perspective view of the helmet mount of Figure 10. Figure 12A is a cross-sectional view of an incorporated speaker enclosure according to another aspect of the present invention and Figures 1 to 6. Figure 12B is a cross-sectional view of an incorporated vibration conduction microphone according to an embodiment of another aspect of the present invention and drawing 3.

Figure 13 is an external view of a typical helmet as used, for example, by fire fighters. Figure 14 is a view of the interior of said typical helmet showing position of the Helmet mounting of Figure 10. Suspended from nape adjustment strap 40 is the Helmet Mount 41 of Figure 10. It will be noted that diaphragm of the incorporated vibration conduction microphone 42 and the diaphragm of the Incorporated speaker enclosure 43 are mounted so that in use they come into contact with the rear of the wearers head.

The inventors have discovered that the vibration conduction microphone and/or the speaker enclosure may be located at the rear of the head. As discussed previously, this location is in contrast to prior art approaches which mount bone conduction transducers at the top of the head which is a potentially dangerous position. As is also the case with the arrangement depicted in Figure 14, the wearers ear is not covered by incorporated speaker enclosure so that the wearer may readily hear ambient sound or wear hearing protection in areas of high ambient noise. The inventors have discovered that, somewhat surprisingly, a speaker enclosure and/or bone conduction microphone according to the invention works well when mounted as shown in Figure 14.

The embodiments of the invention described herein are provided for purposes of explaining the principles thereof, and are not to be considered as limiting or restricting the invention since many modifications may be made by the exercise of skill in the art without departing from the scope of the invention.
